Subject: Analysis of Groundwater from Your Well (Map 24/Lot 54)
Olin Chemical Superfund Site

Dear

At the direction of the United States Environmental Protection Agency (EPA), consultants working for Olin Corporation (which is subject to a consent order with EPA to evaluate environmental conditions in and around property it owns on Eames Street) collected a water sample from your well on November 10, 2009 to analyze for chemical compounds which have been found in groundwater associated with the Olin Chemical Superfund Site. You should have recently received a letter from Olin Corporation conveying the results of their analysis. At that time, EPA also collected a sample for independent analysis.

The laboratory contracted by Olin detected N-nitrosodimethylamine (NDMA) at a concentration of 17.0 nanograms per liter (ng/l), equivalent to 0.000000017 grams per liter or 17.0 parts per trillion. The laboratory contracted by EPA detected NDMA at 22.3 ng/l, which is statistically similar and demonstrates good correlation between Olin and EPA results. These results for NDMA are higher than the 9.4 ng/l detected in October 2008; and similar to the 19.0 and 17.7 ng/l detected in March 2009.

NDMA is a probable human carcinogen and is a contaminant of emerging concern. There are no federal or Massachusetts drinking water standards for NDMA at this time.

The Massachusetts Department of Environmental Protection (MassDEP) has, however issued a "guideline" limit (i.e., a non-enforceable limit) of 10.0 ng/l of NDMA in public drinking water supplies. The concentration of NDMA detected in your well is above the MassDEP guideline limit. Under MassDEP's guideline, public water supply operators are required to report concentrations of NDMA detected at or above 10.0 ng/l, but the MassDEP guideline does not require that actions be taken to limit exposure. Public water supply operators are required to take action if NDMA is detected at or above a concentration of 50.0 ng/l.

Moreover, since this is a federal Superfund site, state guidelines are considered by EPA but do not dictate what actions should be undertaken in response to potential risks to public health. Therefore, consistent with Superfund policy involving chemicals in drinking water for which no federal or state drinking water standard exists, EPA has prepared a focused risk assessment based on the water sample from your well. The

results conclude that if a person drinks an average of 2.0 liters of water per day for 350 days per year for 70 years, and the concentration of NDMA remains constant at 22.3 ng/l for 70 years, that person would have a 9 in 100,000 increased possibility of developing cancer. This risk represents a conservative and cautious estimate of the maximum lifetime exposure risk from drinking the water. Due to the chemical properties of NDMA (e.g., low volatility and low permeability), it does not readily transfer from water to air or from water to skin, therefore inhalation and direct contact with NDMA in groundwater (i.e., showering) do not result in measurable exposure risk. This 9 in 100,000 risk from drinking is below the 1 in 10,000 risk (of developing cancer over a lifetime of exposure) that EPA uses as a benchmark in determining whether use of a drinking water supply should be discontinued immediately.

In addition to NDMA, your well water was also tested by Olin or EPA contracted laboratories for the following chemicals or chemical groups:

- N-nitrosodi-n-propylamine
- N-nitrosodiphynelamine
- Formaldehyde
- Acetaldehyde
- Hydrazine
- Bis 2-Ethylhexylphthalate
- Butylbenzylphthalate
- Di-n-octylphthalate
- Di-n-butylphthalate
- Phenol
- Diethylphthalate
- Dimethylphthalate
- VOCs (volatile organic compounds)[1]
- SVOCs (semi-volatile organic compounds)[2]
- Metals[3]
- Calcium
- Chromium
- Sodium
- Nitrate
- Nitrite
- Chloride
- Sulfate
- Ammonia

Several metals such as copper and magnesium were detected, as well as sodium, however these compounds are often naturally-occurring or plumbing-related, and none were present at concentrations that present a potential health concern. Methyl-t-butyl-ether (MTBE) was also detected at a low concentration below a level of potential health

[1] VOCs include a group of approximately 50 compounds.
[2] SVOCs include a group of approximately 70 compounds.
[3] Metals include a group of approximately 25 compounds.

concern. The MTBE is believed to be from an underground storage tank removed from a nearby service station on Main Street.

The complete EPA analytical results are attached. Positive detections are in **bold text**.

Based on these results, EPA does not recommend any restriction on the use of your well water at this time.

However, due to the continued detection of NDMA in your well, EPA recommends re-testing. A representative from Olin will contact you to schedule another sampling event.

While EPA understands that any concentration of NDMA detected in your drinking water may be of concern, please be aware that NDMA is present in many common foods, beverages and household products. I raise this point not as cause for more concern, but so you can understand that we are all exposed to NDMA on a daily basis, and that a person's baseline exposure to NDMA is not zero.

EPA will revisit this recommendation as additional data are collected.

I would appreciate your continued cooperation. Please call me at 617 918-1247, or contact me by email at dilorenzo.jim @epa.gov should you have any questions.

Sincerely,

James M. DiLorenzo (Jim)
